Computer vision is a Branch of
And acquire the process, analyze and Report the
Image processed and resolution

- a)
- * To learn the directory of Image
 - * To extract the resolution of Image
 - * To develop the feature extraction
 - * Obtain the value of Image processing.

- b
- * Used in X-Ray to learn the injury in the bone
 - * conversion of Image as high resolution

2. They gather the no of images along resolution the
way of shape and colour texture and.
modify the abstract element and such as
developed way to understand the way
of representative processed

- a)
- feature extraction in the image we could
enhance the edge, corner, texture and color
of the image to recapture.

3) To object recognition in vision through the color coding unit is an intimate programmable within the guide lines.

3. There are three levels of image processing used in computer vision

- * Low level image processing
- * mid level image processing
- * High level image processing

a) Low level image processing is in the image enhance the low quality to better quality to optimization

b. mid level.	High level
The image processed to acquire level. use the feature extraction method.	The image resolution should be optimized. import the antimage version to edugate T image

The real world image is converted into digital image and two dimensional matrix of Pixel are the fundamental components of the image

Pixel is a unit of display where the image is processed in object

When the craking or low level of pixel should affect the quality of image ^{or} resolution

5. Using the digital ~~matrix~~ ^{multiplex} as the convention of the matrix of image pixels and formed on digital image

Image sensor is converting light energy to digital image is known as Image Sensor

6. * Digital camera
* Smart phone camera

Sampling and Quantization are done
to convert the continuous analog signal to digital
image as processed as how to interpret and
gathered as possible

Sampling in the process to convert the
Electrical and electronic signal into image
to form processed

Quantization in the process of image to
Prevent the minimization of algorithm and manipulation
and gathered information

The projection of illumination in the way
excluding of further demerits and desirable
to validate the processing

The lens where the camera take the image
the project could appear on the object that is
informative

The role of illumination in image formation
as the pixels are got closer to absorb and
various way to absorbed.

In the image processing of computer vision relate and discriminative value of forming and manages processing

a) The image processing in the an authorized texture should corrected or optimized by the way of length should incorporated

b)	Image processing.	computer version
	image should be optimized.	Image should be pixelized
	convert the image into JPG or IBB.	The image whole recognized.

9. The computer vision can recognize the image as pixel per pixel so it should optimize the problem. shall created

a) x stereo therapy - The tumors should recognize and destroy by the comput. vision...
 x The Tesla - an camera that an AI power to recognize the obstruction

b)

10 The Digital image only should suggest the image perspectives and adopted way of recursion.

a). The pixel are the basic unit display that contains the vision power.

b) The basic unit of image processing is continuous by the value of ~~intensity~~ ~~intensity~~
